

The AECB has expertise in installing and troubleshooting sensors, interpreting data and producing graphs. Sensors report their figures automatically via a web based service which removes the need for site visits.

Our software imports data from the website and allows us to quickly specify the date range, sensors and colour of lines. These graph definitions are saved and can be repeated with new data.

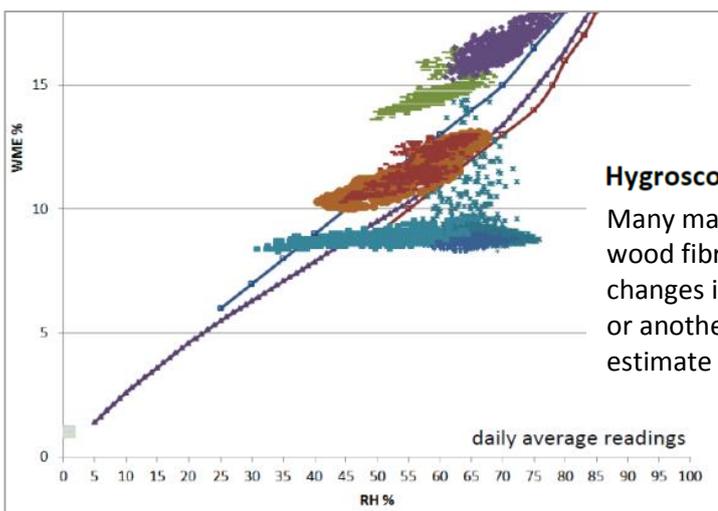

Run Hygro	Write Graphs	Blank Graphs	Series	Current set	1. Treat/Untr	2. WME-RH	3. RH from Glaser	4. RH from WME	5. WME-RH Timber	6. WME in Attic	7. WME in Attic from I
3			11 Kitchen cupboard top	0							R

			3 BROOK - Rafter adjacent bedroom loft hatch	0					G	G	G
			5 BROOK - W ATTIC EAVES AMBIENT	0							B

Our main graphs (above) are moisture content (also known as Wood Moisture Equivalent, WME), RH, temperature and vapour pressure.

Left: Our software defines graphs flexibly and easily.

We also produce tables to show results for a snapshot in time. This helps interpretation by, for example, showing how mould risk, RH and WME are all related.

	WME	RH	T	Mould	VP
S13 GF MID AMBIENT (chest height)	63	17	0	1.23	
S11+2900mm FF joist end	14	72	13	0	1.07
S12 GF BASE AMBIENT	no	data			
S10+2900mm FF WALL BETWEEN JOIST	11	70	13	0	1.06
S09+1500mm GFwall mid height behind IWI	19	80	13	8	1.17
S08+150mm GFwall base in IWI	34	89	11	1955	1.15
S07+100mm GFwall between joists	27	99	10	4912	1.23
S06+00mm GF Joist End	24	96	11	3817	1.23
S05-20mm BASEMENT WALL JOIST LEVEL into wall plate	27	95	11	3734	1.25
S04a-115mm Basement wall below wall plate	26	98	11	4610	1.30
S04+00mm BASEMENT JOIST END UNDERSIDE	19	94	12	3234	1.28
S03-390mm BASEMENT MID HEIGHT	31	99	11	5463	1.31
S02-765mm Basement base	32	105	11	6197	1.37
S01+00mm Basement Ambient Central	17	84	13	1140	1.28

Hygroscopic Effects

Many materials adsorb moisture in a building: timber, cellulose wood fibre and brick. The moisture content in these materials changes in a predictable way, often similar to standard materials or another of our case studies. Monitoring data helps us estimate if the wall is likely to meet safe moisture levels.

Mould Risk

Mould is hard to predict, therefore we compare 2 or 3 criteria for mould according to the situation. They often agree, that doesn't mean that mould is certain, but that the potential risk of it is high. In the tables below red figures indicate a potential problem.

Criteria 1: Johansson et al

	RH at sensor position															
	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
Timber	70	73	83	77	73	88	75	72	79	57	88	75	72	79	57	
Masonry High			74	59			0					83				
Masonry Low	77	0	92	84	87	78	83	94	97	94	93	92				

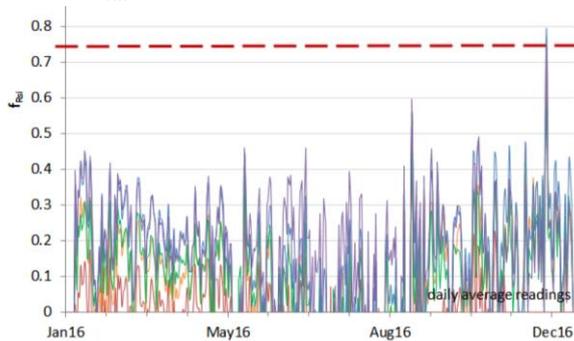

colour grading:
green=dry, yellow, orange and red= more humid

Criteria 2: Sedlbauers Calculation

	Mould Risk at sensor position															
	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
Timber	0	0	220	11	0	785	0	0	1	0	785	0	0	1	0	
Masonry High			1	0			0					23				
Masonry Low	0	0	548	34	119	0	3	537	975	842	608	699				

colour grading:
green=low risk, yellow, orange and red= higher mould risk

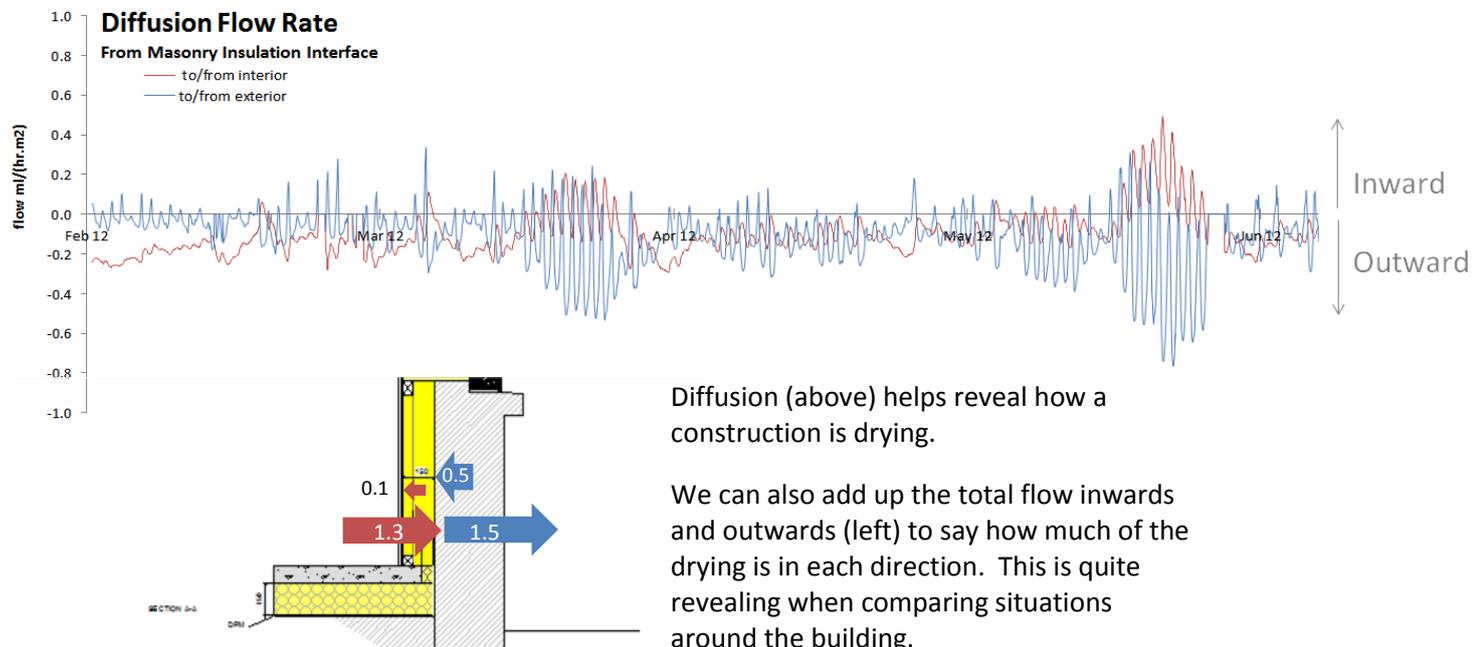

Criteria 3: f_{Rsi} Risk Factor

mould risk below this line

If there are thermal bridges or air is allowed to get behind insulation materials we can also calculate an f_{Rsi} Risk Factor from the readings.

Diffusion

Diffusion (above) helps reveal how a construction is drying.

We can also add up the total flow inwards and outwards (left) to say how much of the drying is in each direction. This is quite revealing when comparing situations around the building.

We also carry out moisture surveys before retrofit to check for moisture issues. These graphs and many more are explained for sample case studies in Module 6 of the AECB Carbonlite Retrofit course.

For more information please contact Tim Martel, who is also a course tutor for this module on tim@aecb.net or call 01453 821444 or 07531288147.
